## Gorensteinness for normal tangent cones of geometric ideals

Tomohiro Okuma (Yamagata Univ.)<br>Kei-ichi Watanabe (Nihon Univ. and Meiji Univ.) Ken-ichi Yoshida (Nihon Univ.) .

The $43{ }^{\text {rd }}$ Japan Symposium on Commutative Algebra at Osaka University

November 14, 2022

## Notation

Throughout this talk, we assume

## Assumption ( $*$ )

- $(\boldsymbol{A}, \mathfrak{m})$ : excellent normal local domain.
- $\boldsymbol{A} \supset \boldsymbol{K}=\overline{\boldsymbol{K}}$ : algebraically closed field
- $\operatorname{dim} \boldsymbol{A}=\mathbf{2}, \boldsymbol{A}$ is not regular
- I is an m-primary integrally closed ideal
- $\boldsymbol{Q}=(\mathbf{a}, \boldsymbol{b})$ is a minimal reduction of $\boldsymbol{I}$
$\boldsymbol{\exists}$ resolution of sing. $\boldsymbol{f}: \boldsymbol{X} \rightarrow \operatorname{Spec} \boldsymbol{A}, \boldsymbol{\exists} \boldsymbol{Z}$ an anti-nef cycle on $\boldsymbol{X}$ s.t.

$$
O_{X}=O_{X}(-Z), \quad I=H^{0}\left(X, O_{X}(-Z)\right)
$$

Then we denote it by $\boldsymbol{I}=I_{\boldsymbol{Z}}$.
(So, $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}}$ means that $\boldsymbol{I}$ is an $\mathbf{m}$-primary integrally closed ideal)

## Two normal reduction numbers

## Definition 1.1 (Normal reduction numbers (cf. [OWY4]))

- The relative normal reduction number of $I$ is defined by

$$
\operatorname{nr}(I):=\min \left\{r \geq 1 \mid \overline{I^{r+1}}=Q \bar{Q}\right\}
$$

- The normal reduction number of $\boldsymbol{I}$ is defined by

$$
\overline{\mathbf{r}}(I):=\min \left\{r \geq 1 \mid \overline{I^{N+1}}=Q \bar{I}^{N}(\forall N \geq r)\right\}
$$

Then $\mathbf{1} \leq \mathbf{n r}(\boldsymbol{I}) \leq \overline{\mathbf{r}}(I)$.
For any given $\boldsymbol{r} \geq \mathbf{3}, \boldsymbol{\exists I}=\boldsymbol{I} \boldsymbol{Z} \subset \boldsymbol{A}$ : s.t. $\mathbf{1}=\mathbf{n r}(\boldsymbol{I})<\boldsymbol{r}=\overline{\mathbf{r}}(\boldsymbol{I})$ (cf. [OWY5]).

## $q(n l)$

For any $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{z}}$ and a positive integer $\boldsymbol{n}$, we put

$$
\boldsymbol{q}(n I):=\operatorname{dim}_{K} H^{1}\left(O_{X}(-n Z)\right)
$$

$\boldsymbol{p}_{\boldsymbol{g}}(\boldsymbol{A}):=\operatorname{dim}_{\boldsymbol{K}} \boldsymbol{H}^{\mathbf{1}}\left(\boldsymbol{O}_{\boldsymbol{X}}\right)=\mathbf{q}(\mathbf{O})$ is called a geometric genus.

## Proposition 1.2 (cf. [OWY1,OWY4])

For any minimal reduction $\mathbf{Q}$ of $\boldsymbol{I}$,
(1) $0 \leq q(I) \leq p_{g}(A)$.
(2) $k \geq 0 \Rightarrow q(k I) \geq q((k+1) I)$.
(3) $\boldsymbol{q}(n \mathbf{I})=\boldsymbol{q}((n+1) \boldsymbol{I}) \Longrightarrow \boldsymbol{q}(n \mathbf{l})=\boldsymbol{q}(m \boldsymbol{l})(\forall m \geq n)$.

Put $\mathbf{q}(\infty \mathbf{l})=\mathbf{q}(\boldsymbol{n l})$ for large enough $\boldsymbol{n}$.
(4) $\mathbf{2} \cdot \mathbf{q}(k I)+\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{I^{k+1}} / \mathbf{Q I ^ { \boldsymbol { k } }}\right)=\mathbf{q}((\boldsymbol{k}+\mathbf{1}) \boldsymbol{I})+\mathbf{q}((\boldsymbol{k}-\mathbf{1}) \boldsymbol{I})$.

## $\overline{\mathrm{r}}(I)$ and $\mathrm{q}(n I)$

## Proposition 1.3 ([OWY5, Proposition 2.2])

For $\boldsymbol{I}=I_{\mathbf{Z}}$, we have
(1) $\operatorname{nr}(I)=\min \left\{n \in \mathbb{Z}_{+} \mid q((n-1) I)-q(n I)=q(n I)-q((n+1) I)\right\}$.
(2) $\overline{\mathbf{r}}(I)=\min \left\{n \in \mathbb{Z}_{+} \mid \boldsymbol{q}((n-1) I)=\boldsymbol{q}(n I)\right\}$.
(3) $\overline{\mathbf{r}}(I) \leq \boldsymbol{p}_{g}(A)+1$. If equality holds, then $\mathbf{n r}(I)=\mathbf{1}$.

For instance, if $\overline{\mathbf{r}}(\boldsymbol{I})=\mathbf{2}$, then $\mathbf{q}(\mathbf{2 I})=\mathbf{q}(\boldsymbol{I})$ holds. Hence
$\mathbf{2} \cdot \mathbf{q}(I)+\ell_{A}\left(\overline{I^{2}} / Q I\right)=\boldsymbol{q}((2 I)+\boldsymbol{q}(0 I)$
$\Rightarrow \quad \ell_{A}\left(\overline{I^{2}} / Q I\right)=p_{g}(A)-q(I)$
$\square \exists I=I_{z} \subset A$ s.t. $p_{g}(A)=2>q(I)=1>q(2 I)=\cdots q(\infty I)=0$.
So $1=n r(I)<\bar{r}(I)=3$ and $p_{g}(A)=2$.

## Normal Hilbert coefficients

## Proposition 1.4 ([OWY2, Theorem 3.2])

The normal Hilbert polynomial $\overline{\boldsymbol{P}}_{\mathbf{l}}(\boldsymbol{n})$ can be written as the folloiwing form:

$$
\bar{P}_{l}(n)=\bar{e}_{0}(I)\binom{n+2}{2}-\bar{e}_{1}(I)\binom{n+1}{1}+\bar{e}_{2}(I)
$$

(1) $\bar{P}_{I}(n)=\ell_{A}\left(A / \overline{I^{n+1}}\right)\left(\forall n \geq p_{g}(A)-1\right)$.
(2) $\bar{e}_{0}(I)=e_{0}(I)=-Z^{2}$.
(3) $\bar{e}_{1}(I)-\bar{e}_{0}(I)+\ell_{A}(A / I)=p_{g}(A)-q(I)$.
(4) $\overline{\mathbf{e}}_{2}(I)=p_{g}(A)-q(n I)=p_{g}(A)-q(\infty I)\left(\forall n \geq p_{g}(A)\right)$.

- Each $\overline{\mathbf{e}}_{i}(\boldsymbol{I})$ is called a normal Hilbert coefficient.

## Some graded algebra (normal tangent cone etc.)

## Definition 1.5

For $\boldsymbol{I}=I_{\mathbf{Z}}$,
(1) $\boldsymbol{G}(I):=\bigoplus_{n \geq 0} I^{n} / I^{n+1}$ : the associted graded ring of $I$.
(2) $\overline{\boldsymbol{G}}(\boldsymbol{I}):=\bigoplus_{\boldsymbol{n} \geq 0} \overline{I^{\boldsymbol{n}}} / \overline{\boldsymbol{I}^{n+1}}$ : the normal tangent cone of $\boldsymbol{I}$.

## Question: When is $\overline{\mathbf{G}}(I)$ Gorenstein

In this talk, we consider the following question for 'geometric' ideals.

## Question 1.6

(1) When is $\overline{\mathbf{G}}(\boldsymbol{I})$ Cohen-Macaulay?
(2) When is $\overline{\boldsymbol{G}}(\boldsymbol{I})$ Gorenstein?

The above question is related to our previous reserach, which the following observation shows.

## Proposition 1.7

If $\overline{\mathbf{G}}(\boldsymbol{I})$ is Cohen-Macaulay, then $\mathbf{n r}(\boldsymbol{I})=\overline{\mathbf{r}}(\boldsymbol{I})$.

## Example: $\overline{\mathbf{G}}(I)$ is not CM

## Ex 1.8

Let $\boldsymbol{K}$ be a filed of $\operatorname{char} \boldsymbol{K} \neq \mathbf{2 , 3}$, and let $\boldsymbol{A}=\boldsymbol{K}\left[\left[\mathbf{x y}, \boldsymbol{x z}, \boldsymbol{y}^{2}, \boldsymbol{y z}, \boldsymbol{z}^{2}\right]\right]$ with $\boldsymbol{x}^{2}=\boldsymbol{y}^{6}+\boldsymbol{z}^{6}$. That is, $\boldsymbol{A}=\boldsymbol{K}[\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}, \boldsymbol{d}, \boldsymbol{e}] / \mathfrak{a}$, where $\mathfrak{a}$ is generated by the following polynomials:

$$
\begin{array}{lll}
a^{2}-d^{4}-d e^{3}, & a b-c d^{3}-c e^{3}, & b^{2}-d^{3} e-e^{4} \\
a c-b d, & a e-b c, & d e-c^{2}
\end{array}
$$

Then $\boldsymbol{A}$ is an excellent normal local domain with $\boldsymbol{v}=\boldsymbol{e}+\boldsymbol{d} \mathbf{- 1}=\mathbf{5}$.

If we put $I=\left(x y, x z, y z, y^{2}, z^{4}\right)=\left(a, b, c, d, e^{2}\right) \supset \boldsymbol{Q}=\left(c, d-e^{2}\right)$, then $\boldsymbol{I}=\boldsymbol{I} \boldsymbol{z}$ and $\mathbf{1}=\mathbf{n r}(\boldsymbol{I})<\overline{\mathbf{r}}(\boldsymbol{I})=\mathbf{3}$.
In particular, $\overline{\boldsymbol{G}}(\boldsymbol{I})$ is NOT Cohen-Macaulay.
On the other hand, $\mathbf{G}(\boldsymbol{I})$ is Cohen-Macaulay.

## $\boldsymbol{p}_{\mathrm{g}}$-ideal

## Definition 1.9 ([OWY1])

An ideal $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}}$ is called a $\boldsymbol{p}_{g}$-ideal if it satisfies one of the following equivalent conditions:
(1) $\bar{r}(I)=1$.
(2) $q(I)=p_{g}(A)$.
(3) $\overline{\mathbf{e}}_{1}(I)-\bar{e}_{0}(I)+\ell_{A}(A / I)=0$.
(4) $\bar{e}_{2}(I)=0$.
(6) I is normal and stable.

- $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}}$ is normal if $\overline{\boldsymbol{I}^{\boldsymbol{n}}}=\boldsymbol{I}^{\boldsymbol{n}}$ for every $\boldsymbol{n} \geq \mathbf{1}$.
- $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}}$ is stable if $\boldsymbol{I}^{\mathbf{2}}=\boldsymbol{Q} \boldsymbol{I}$ for some minimal reduction $\boldsymbol{Q}$ of $\boldsymbol{I}$.

## Proposition 1.10

$\boldsymbol{A}$ is a rational singularity (i.e. $\left.\boldsymbol{p}_{\mathbf{g}}(\boldsymbol{A})=\mathbf{0}\right) \Longleftrightarrow \forall I=\boldsymbol{I}_{\mathbf{Z}}$ is a $\boldsymbol{p}_{\boldsymbol{g}}$-ideal.

## $\overline{\boldsymbol{G}}(I)$ of $p_{g}$-ideals

## Proposition 1.11 ([ORWY])

If I is a $p_{g}$-ideal, then
(1) $\overline{\mathbf{G}}(\boldsymbol{I})=\mathbf{G}(\boldsymbol{I})$ is Cohen-Macaulay.
(2) $\overline{\mathcal{R}}(\boldsymbol{I})=\mathcal{R}(I)$ is a Cohen-Macaulay normal domain.

An ideal $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}}$ is called good if $\boldsymbol{I}$ is stable with $\boldsymbol{I}=\boldsymbol{Q}: \boldsymbol{I}$.

## Theorem 1.12

Suppose that I is a $p_{g}$-ideal. Then the following conditions are equivalent:
(1) $\overline{\mathbf{G}}(\boldsymbol{I})=\boldsymbol{G}(\boldsymbol{I})$ is Gorenstein.
(2) I is good.

## Elliptic ideal

## Definition 1.13 ([OWRY, Theorem 3.2])

An ideal $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{z}}$ is called a elliptic ideal if it satisfies one of the following equivalent conditions:
(1) $\overline{\mathbf{r}}(I)=2$.
(2) $p_{g}(A)>q(I)=q(\infty I)$.
(3) $\bar{e}_{1}(I)-\bar{e}_{0}(I)+\ell_{A}(A / I)=\bar{e}_{2}(I)>0$.

## Theorem 1.14 ([ORWY, Corollary 3.7])

$\boldsymbol{A}$ is an elliptic singularity $\Longrightarrow \overline{\mathbf{r}}(\boldsymbol{I}) \leq \mathbf{2}$ for any $\boldsymbol{I}=\boldsymbol{I}_{\mathbf{z}}$.
How about the converse?

## Main Question

## Question 1.15

Assume that $I$ is an elliptic ideal.
(1) When is $\bar{G}(I)$ Cohen-Macaulay?
(2) When is $\bar{G}(I)$ Gorenstein?

## Theorem 1.16 ([ORWY], Huneke)

If $\boldsymbol{I}$ is elliptic ideal, then $\overline{\mathbf{G}}(\boldsymbol{I})$ is Cohen-Macaulay.

## Main result

The following theorem gives a characterization for Gorensteinness of $\overline{\mathbf{G}}(\boldsymbol{I})$ for any elliptic ideal I.

## Theorem 2.1

Assume $\boldsymbol{A}$ is Gorenstein and $\overline{\mathbf{r}}(\boldsymbol{I})=\mathbf{2}$.
Then the following conditions are equivalent:
(1) $\bar{G}(I)$ is Gorenstein.
(2) $\boldsymbol{Q}: \boldsymbol{I}=\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}}$ holds true.
(3) $\boldsymbol{\ell}_{\boldsymbol{A}}\left(\boldsymbol{I}^{2} / \mathbf{Q}\right)=\boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \boldsymbol{I})$ holds true.
(4) $\overline{\mathbf{e}}_{\mathbf{2}}(\boldsymbol{I})=\boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \mathbf{I})$ holds true.
(6) $K \mathbf{Z}=-\boldsymbol{Z}^{2}$, that is, $\chi(Z)=\mathbf{0}$.

## Sketch of the proof $(2) \Longrightarrow(1)$

Theorem $1.16 \Rightarrow \overline{\boldsymbol{G}}:=\overline{\mathbf{G}}(\boldsymbol{I})$ is Cohen-Macaulay.
Then $\boldsymbol{a}^{*}, \boldsymbol{b}^{*} \in \overline{\boldsymbol{G}}$ forms a $\overline{\mathbf{G}}$-sequence, where $\boldsymbol{Q}=(\boldsymbol{a}, \boldsymbol{b})$.
If we put $\boldsymbol{B}=\overline{\boldsymbol{G}} /\left(\boldsymbol{a}^{*}, \boldsymbol{b}^{*}\right) \cong \boldsymbol{A} / \boldsymbol{I} \oplus \boldsymbol{I} /\left(\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}}\right) \oplus\left(\boldsymbol{Q}+\overline{\mathbf{I}^{2}}\right) / \boldsymbol{Q}$, then
$\bar{G}$ : Gorenstein $\Longleftrightarrow$ B: Gorenstein.
$(2) \Rightarrow(1): E T S: \operatorname{dim}_{K} \operatorname{Soc}(B)=1$.
Let $\boldsymbol{x}^{*} \in \operatorname{Soc}(\boldsymbol{B})$, a homogeneous element.
When $\boldsymbol{x}^{*} \in \boldsymbol{B}_{0}, \boldsymbol{x}^{*} \boldsymbol{B}_{\mathbf{2}}=\mathbf{0} \Rightarrow \boldsymbol{x} \in \boldsymbol{Q}:\left(\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}}\right) \stackrel{(2)}{=} \boldsymbol{Q}:(\boldsymbol{Q}: \boldsymbol{I})=\boldsymbol{I}$.
When $x^{*} \in B_{1}, x^{*} B_{1}=0 \Rightarrow x \in Q: I=Q+\overline{I^{2}}$.
Hence $\operatorname{Soc}(\boldsymbol{B}) \subset \operatorname{Soc}\left(\boldsymbol{B}_{2}\right) \cong \boldsymbol{K}$, as required.
(1) $\overline{\boldsymbol{G}}(I)$ is Gorenstein.
(2) $\boldsymbol{Q}: \boldsymbol{I}=\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}}$.

## Sketch of the proof $(1) \Longrightarrow(2) \Longleftrightarrow(3)$

(Obs i) Huneke-Itoh's theorem (i.e. $\boldsymbol{Q} \cap \overline{\boldsymbol{I}^{2}}=\boldsymbol{Q} \boldsymbol{I}$ )
$\Longrightarrow \boldsymbol{\ell}_{\boldsymbol{A}}\left(\boldsymbol{B}_{2}\right)=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}} \boldsymbol{Q}\right)=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{\boldsymbol{I}^{2}} / \mathbf{Q} \cap \overline{\boldsymbol{I}^{2}}\right)=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{\boldsymbol{I}^{2}} / \boldsymbol{Q}\right)$.
(Obs ii) Matlis duality
$\Rightarrow \boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{Q}: \boldsymbol{I} / \boldsymbol{Q})=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\boldsymbol{K}_{\boldsymbol{A} / \mathbf{I}}\right)=\boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \boldsymbol{I})=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\boldsymbol{B}_{0}\right)$.
(Obs iii) $\overline{\mathbf{r}} \boldsymbol{I})=\mathbf{2} \Rightarrow \overline{I^{2}} \subset \overline{I^{3}}=\mathbf{Q} \boldsymbol{I}^{2} \Rightarrow \boldsymbol{Q}+\overline{\boldsymbol{I}^{2}} \subset \boldsymbol{Q}: \boldsymbol{I}$.

$$
\therefore \ell_{A}\left(B_{0}\right)-\ell_{A}\left(B_{2}\right)=\ell_{A}\left(Q: I / Q+\overline{I^{2}}\right)=\ell_{A}\left(\overline{I^{2}} / Q I\right)-\ell_{A}(A / I) .
$$

Hence this implies $(\mathbf{1}) \Longrightarrow(2) \Longleftrightarrow(3)$.
(1) $\overline{\boldsymbol{G}}(\boldsymbol{I})$ is Gorenstein.
(2) $\boldsymbol{Q}: \mathbf{I}=\boldsymbol{Q}+\overline{\boldsymbol{I}^{2}}$.
(3) $\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{I^{2}} / Q I\right)=\boldsymbol{\ell}_{\boldsymbol{A}}(\mathbf{A} / \boldsymbol{I})$.

## Sketch of the proof $(3) \Longleftrightarrow(4) \Longleftrightarrow(5)$

Assume $\overline{\mathbf{r}}(I)=\mathbf{2}$. Then $\boldsymbol{q}(I)=\mathbf{q}(\mathbf{2 I})=\boldsymbol{q}(\infty I)$.
(Obs i) Prop. $1.2 \Longrightarrow \boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{I^{2}} / Q I\right)=\boldsymbol{p}_{\boldsymbol{g}}(A)-\boldsymbol{q}(I)$.
(Obs ii) Prop. $1.4 \Longrightarrow \overline{\boldsymbol{e}}_{\mathbf{2}}(\boldsymbol{I})=\boldsymbol{p}_{\boldsymbol{g}}(\boldsymbol{A})-\boldsymbol{q}(\infty \boldsymbol{I})\left(=\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{\boldsymbol{I}^{2}} / \boldsymbol{Q I}\right)\right)$.
(Obs iii) Kato's Riemann-Roch formula

$$
\begin{aligned}
& \ell_{A}(A / I)+q(I)=\chi(Z)+p_{g}(A), \text { where } \chi(Z)=-\frac{Z^{2}+K Z}{2} . \\
\Rightarrow & \chi(Z)=\ell_{A}(A / I)-\left\{p_{g}(A)-q(I)\right\} .
\end{aligned}
$$

Hence $\quad \boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \boldsymbol{I})-\boldsymbol{\ell}_{\mathbf{A}}\left(\overline{\boldsymbol{I}^{2}} / Q I\right)=\boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \boldsymbol{I})-\overline{\mathbf{e}}_{2}(\boldsymbol{I})=\chi(\boldsymbol{Z})$.
(3) $\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{I^{2}} / Q I\right)=\boldsymbol{\ell}_{A}(\mathbf{A} / \mathbf{I})$.
(4) $\bar{e}_{2}(I)=\boldsymbol{\ell}_{\boldsymbol{A}}(\boldsymbol{A} / \boldsymbol{I})$.
(5) $\chi(\boldsymbol{Z})=\mathbf{0}$, that is, $\boldsymbol{K} \boldsymbol{Z}=\boldsymbol{-} \boldsymbol{Z}^{\mathbf{2}}$.

## Strongly elliptic ideal

## Definition 2.2 ([OWRY, Theorem 3.9])

An ideal $\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{z}}$ is called a strongly elliptic ideal if it satisfies one of the following equivalent conditions:
(1) $\overline{\mathbf{r}}(\boldsymbol{I})=2$ and $\boldsymbol{\ell}_{\boldsymbol{A}}\left(\overline{\boldsymbol{I}^{2}} / Q I\right)=\mathbf{1}$ for some min. reduction $\boldsymbol{Q}$ of $\boldsymbol{I}$.
(2) $p_{g}(A)-1=q(I)=q(\infty I)$.
(3) $\bar{e}_{2}(I)=1$.

A (resp. A Gorenstein) local ring $\boldsymbol{A}$ is called a strongly elliptic singularity (resp. minimally elliptic singularity) if $\boldsymbol{p}_{\mathrm{g}}(\boldsymbol{A})=\mathbf{1}$.

## Theorem 2.3 ([ORWY, Theorem 3.14])

$\boldsymbol{A}$ is a strong elliptic singularity
$\Rightarrow$ any $\boldsymbol{I}=\mathbf{I}_{\mathbf{Z}}$ is either a $\mathbf{p}_{\mathbf{g}}$-ideal or a strongly elliptic ideal.

## When is $\overline{\mathbf{G}}(\mathfrak{m})$ Gorenstein

In what follows, we always assume that $\boldsymbol{A}$ is Gorenstein.
When is $\overline{\boldsymbol{G}}(\mathfrak{m})$ Gorenstein?

## Proposition 2.4

(1) $\overline{\mathbf{r}}(\mathfrak{m}) \leq \mathbf{2} \Longrightarrow \overline{\mathbf{G}}(\mathrm{m})$ is Gorenstein.
(2) If $\boldsymbol{p}_{g}(A) \leq \mathbf{2} \Rightarrow \overline{\boldsymbol{G}}(\mathrm{m})$ is Gorenstein.

If $\overline{\mathbf{r}}(\mathfrak{m})=\mathbf{1}$, then $\mathfrak{m}$ is good.
If $\overline{\mathbf{r}}(\mathbf{m})=\mathbf{2}$, then $\mathfrak{m}$ satisfies the condition of the theorem.
$\boldsymbol{p}_{\mathbf{g}}(\boldsymbol{A})=\mathbf{2}(\boldsymbol{A}$ :Gor. $) \stackrel{\text { Yau }}{\Rightarrow} \boldsymbol{A}$ : elliptic $\stackrel{\text { Okuma }}{\Rightarrow} \overline{\mathbf{r}}(\boldsymbol{I}) \leq \mathbf{2}$ for $\forall I=\boldsymbol{I}_{\mathbf{z}}$.

## Geometric genus

Lemma 2.5
$A=K[[x, y, z]] /\left(x^{a}+y^{b}+z^{c}\right)$

$$
\Longrightarrow p_{g}(A)=\sum_{n=0}^{a(A)} \operatorname{dim}_{K} A_{n}
$$

For example, we consider $A=\mathbb{C}[[x, y, z]] /\left(x^{2}+y^{3}+z^{6 g+1}\right)$. Put $\operatorname{deg}(\boldsymbol{x})=\mathbf{3}(\mathbf{6 g}+\mathbf{1}), \operatorname{deg}(\boldsymbol{y})=\mathbf{2}(\mathbf{6 g}+\mathbf{1})$, and $\operatorname{deg}(\boldsymbol{z})=\mathbf{6}$. Then $a(A)=6(6 g+1)-\{\mathbf{3}(6 g+1)+2(6 g+1)+6\}=6 g-5$.

$$
\therefore p_{g}(A)=\sum_{n=0}^{6 g-5} \operatorname{dim}_{K} A_{n}=\sharp\left\{1, z, z^{2}, \ldots, z^{g-1}\right\}=g .
$$

## When is $\overline{\mathbf{G}}(\mathfrak{m})$ Gorenstein: Examples (1)

## Ex 2.6

Let $\mathbf{g} \geq 1$ be an integer.
(1) $A=\mathbb{C}[[x, y, z]] /\left(x^{2}+y^{3}+z^{6 g+1}\right)$.

$$
p_{g}(A)=g, \bar{r}(\mathfrak{m})=1,
$$

$$
\overline{\boldsymbol{G}}(\mathfrak{m})=\boldsymbol{G}(\mathfrak{m}) \cong \boldsymbol{K}[\boldsymbol{X}, \boldsymbol{Y}] /\left(\boldsymbol{X}^{2}\right) \text { is Gorenstein. }
$$

(2) $A=\mathbb{C}[[x, y, z]] /\left(x^{2}+y^{4}+z^{4 g}\right)$

$$
\begin{aligned}
& p_{g}(A)=g, \bar{r}(\mathfrak{m})=2, \bar{G}(\mathfrak{m}) \text { is Gorenstein. Indeed, } \\
& \bar{G}(\mathfrak{m}) \cong \begin{cases}\mathbb{C}[X, Y, Z] /\left(X^{2}+Y^{4}+Z^{4}\right) & \text { (if } \boldsymbol{g}=\mathbf{1}) \\
\mathbb{C}[X, Y, Z] /\left(X^{2}+Y^{4}\right) & \text { (o.e.) }\end{cases}
\end{aligned}
$$

## When is $\overline{\mathbf{G}}(\mathfrak{m})$ Gorenstein: Examples (2)

(1) $\exists \boldsymbol{A}$ which satisfies $\overline{\mathbf{r}}(\mathbf{m})=\mathbf{3}$ and $\overline{\mathbf{G}}(\mathbf{m})$ is Not Gorenstein.
(2) $\exists \boldsymbol{A}$ which satisfies $\boldsymbol{p}_{\boldsymbol{g}}(\boldsymbol{A})=\mathbf{3}$ and $\overline{\boldsymbol{G}}(\mathbf{m})$ is Not Gorenstein.

$$
\begin{aligned}
& \text { Ex } 2.7 \\
& \boldsymbol{A}=\mathbb{C}[[\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z}]] /\left(\mathbf{x}^{\mathbf{3}}+\boldsymbol{y}^{\mathbf{5}}+\mathbf{z}^{\mathbf{5}}\right) \text {. } \\
& \text { Then } \overline{\mathbf{r}}(\mathfrak{m})=\boldsymbol{p}_{\boldsymbol{g}}(\boldsymbol{A})=\mathbf{3} \text {, and that } \overline{\boldsymbol{G}}(\mathfrak{m}) \text { is Not Gorenstein }
\end{aligned}
$$

## Application: Elliptic ideals in Gorenstein elliptic singularity

Using geometric tools, we give the following finiteness therorem.

## Theorem 2.8

Assume that $\boldsymbol{A}$ is an elliptic Gorenstein singularity.
If we put $\mathcal{G}_{\text {ell }}:=\left\{\boldsymbol{I}=\boldsymbol{I}_{\boldsymbol{Z}} \subset \boldsymbol{A} \mid \boldsymbol{I}\right.$ is elliptic, $\overline{\boldsymbol{G}}(\boldsymbol{I})$ is Gorenstein $\}$, then we have $\#\left(\mathcal{G}_{\text {ell }}\right) \leq \boldsymbol{p}_{g}(A)$.
$\boldsymbol{A}$ is called an elliptic singularuty if $\chi(\boldsymbol{D}) \geq \mathbf{0}$ for any cycle $\boldsymbol{D}>\mathbf{0}$ and $\chi(\boldsymbol{F})=\mathbf{0}$ for some cycle $\boldsymbol{F}>\mathbf{0}$.

Question 2.9
For any Gorentein local ring $\boldsymbol{A}$, is the set $\mathcal{G}_{\text {ell }}$ above a finite set?

## Application: Elliptic ideals in Gorenstein elliptic singularity

## Ex 2.10

Let $\boldsymbol{A}=\mathbb{C}[[\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z}]] /\left(\boldsymbol{x}^{2}+\boldsymbol{z}\left(\boldsymbol{z}^{\mathbf{4 n + 2}}+\boldsymbol{y}^{\mathbf{4}}\right)\right)$ and

$$
B=\mathbb{C}[x, y, z] /\left(x^{2}+y^{3}+z^{6(2 n+1)}\right) .
$$

Then both $\boldsymbol{A}$ and $\boldsymbol{B}$ are elliptic Gorenstein singularities with the same resolution graph.
(1) $p_{g}(A)=n+1$ and $\sharp\left(G_{\text {ell }}\right)=n$.

In fact, $\mathcal{G}_{\text {ell }}=\left\{\left(x, y, z^{j}\right) \mid j=1,2, \ldots, n\right\}$.
(2) $p_{g}(B)=2 n+1$ and $G_{\text {ell }}=\emptyset$.

Note: $\overline{\boldsymbol{G}}(\mathfrak{m})$ is Gorenstein. But $\mathfrak{m} \subset \boldsymbol{B}$ is not an elliptic ideal but a good $p_{g}$-ideal.

Thank you very much for your attention!
